

Study Beta 2026 Protocol v1.4

Exploratory feasibility protocol | Sakura Clinical | Internal synthetic scenario

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Objectives

Assess feasibility of the planned visit workflow, completeness of synthetic assessments, and suitability of review triggers for a future design discussion.

Analysis

Descriptive summaries and implementation observations only. No hypothesis-confirming testing or clinical decision making is represented.
