

Adaptive Review Plan

Planned governance checkpoints for a synthetic exploratory feasibility study

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Review cadence

A multidisciplinary synthetic review occurs after enrollment of 12, 24, and 36 synthetic records. The review confirms operational completeness and whether the 2.5 mg threshold requires discussion.

Outputs

Meeting notes record feasibility observations, unresolved questions, and amendments for simulation purposes.
