

Assessment Manual

Synthetic assessor guidance for structured feasibility observations

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Assessment domains

Visit completion, simulated data completeness, protocol deviation categorization, and reviewer query closure are captured using neutral operational language.

Quality controls

Assessors use source-independent reconciliation and document uncertainty as an operational observation, not a clinical result.
