

Dose Review Rules

Protocol-defined review threshold: 2.5 mg

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Rule set

The 2.5 mg boundary prompts a documented review of synthetic operational evidence. No automatic dose action, recommendation, or participant-level decision is implied.

Escalation record

The review chair records rationale, data completeness, and whether a protocol clarification is needed.
