

Monitoring Plan

Risk-proportionate monitoring for synthetic operational records

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Monitoring focus

The monitor checks version control, consent-template completion, synthetic source traceability, and review-threshold documentation.

Issue handling

Findings are logged, classified by operational impact, and closed through documented corrective actions in the simulated study environment.
