

Protocol Synopsis

Study Beta 2026 exploratory feasibility study

Study frame

Study Beta 2026 is a wholly synthetic, exploratory feasibility study conducted for scenario design and operational training. The synthetic cohort is 36 participants, allocated 18/18 across two blinded review paths.

Dose review boundary

A 2.5 mg exposure remains a protocol-defined review threshold. Crossing the threshold triggers a scheduled evidence review; it is not an efficacy claim or an instruction for care.

Decision discipline

All observations are synthetic. The study is not confirmatory, does not establish safety or effectiveness, and does not provide medical advice.

Reference anchor

Study Alpha snapshot dated 2026-09-02 with synthetic cohort 48 is a separate contextual anchor only and is not pooled with Beta analyses.

Design summary

Two parallel synthetic review paths; total synthetic cohort 36 (18/18); scheduled reviews at operational milestones.

Key limitation

This synopsis is a simulated research artifact. It contains no real participants, clinical recommendations, or medical claims.
